1. Eggs were stored in an atmosphere containing 0 or 2 p. 100 of carbon dioxide. Without 
\( \text{CO}_2 \), the thinning of thick egg white was accompanied by a decrease of both total ovomucin and 
NANA content of this precipitate (fig. 1, 2) while its pH value was enhanced (table 1). The 
decrease of total ovomucin content excepted, all these alterations were suppressed by 2 p. 100 
of \( \text{CO}_2 \) in the storage atmosphere.

2. Eggs produced by hens made acidotic by a diet containing 3 p. 100 of \( \text{NH}_4\text{Cl} \) were also 
studied. Increase in the height of the thick white was accompanied by a small, non significant 
increase in precipitable ovomucin complex without any variation of its NANA content (table 2).

3. These results are discussed in relation to the hypothesis of Robinson (1972) which sup-
posed that NANA can participate in the gel structure of the thick white. It is proposed that, 
during egg storage, \( \text{CO}_2 \) acts through a protection of the \( \beta \)-components of ovomucin (carbohy-
drate rich fraction).

4. Attention is called on the specific effect of divalent cations in the control of the height 
of the thick egg white gel according to the previous hypothesis of Sauveur (1970 and 1971).

THE EFFECT OF IN VITRO EGG PLUMPING 
ON EGG WHITE PHYSICO-CHEMICAL PROPERTIES

B. SAUVEUR

avec la collaboration technique de Mme Huguette Antoine

Station de Recherches avicoles, 
Centre de Recherches de Tours, I. N. R. A., 
Nouzilly, 37380 Monnaie

The purpose of this investigation was to study the possibilities of modifying the physico-
chemical properties of the egg-white by plumping the uterine eggs in artificial solutions. Soft 
shelled eggs were expelled out of uterus six hours after the former oviposition and immersed 
during four hours in either distilled water, or solutions of \( \text{NaCl} \), \( \text{CaCl}_2 \), \( \text{MgCl}_2 \), and glucose at 
300 mOsm (ten eggs in each treatment).

The hourly weight gain of the egg and water content of the egg-white after four hours are 
reported in table 1. Whatever the nature of the solution, the rate of plumping was higher during 
the first two hours than during the two following. The final egg-white water content was as 
follows : Glucose < \( \text{MgCl}_2 \) < \( \text{CaCl}_2 \) < \( \text{NaCl} \) < \( \text{H}_2\text{O} \). This result is in good agreement with general 
laws of water imbibing power of polyelectrolytes ; it confirms that divalent cations (Mg and Ca) 
are bound more extensively than Na to egg-white organic matter.

Table 2 refers to some properties of egg-white, estimated after the in vitro hydratation. 
The height of thick white (first column) was increased by \( \text{CaCl}_2 \), \( \text{MgCl}_2 \) or glucose, relatively 
to \( \text{H}_2\text{O} \) or \( \text{NaCl} \). So it was quite possible to modify this very important character of egg-white 
quality, without any alteration of protein content. It appeared that high values of Haugh units 
required a great cohesion of peptidic chains (obtainable by high levels of Ca and Mg) and, conse-
quently, a low water content of the thick white.

The reported values of viscosity have to be considered with caution because they were
obtained with an ordinary Ostwald viscometer after blending of egg-white at high speed. Anyhow, concentrations of proteins and minerals in egg-white seemed to be too high to allow a simple application of general laws governing the viscosity of glycoproteins.

The study of egg-white osmotic pressure and mineral content (tables 3 and 4) showed that, with NaCl treatment at least, the egg-white plumping occurred according to the Donnan equilibrium. The increase of osmotic pressure (320 mOsm) observed with NaCl relatively to CaCl₂ or MgCl₂ (301 mosm) was a supplementary evidence for the binding of divalent cations to organic molecules.

VI. — Economics

ECONOMIC INVESTIGATIONS OF THE TECHNICAL INSTITUTE FOR AVICULTURE

J.-L. IRONDE

Division économique, I. T. A. V. I.,
28, Rue du Rocher,
75008 Paris

Forecasting of the future necessitates a thorough analysis of the evolution mechanisms. The task of the I. T. A. V. I. is therefore to examine closely the various elements necessary to establish the synthesis of a global phenomenon. With this end in view, the Division of Economics of I. T. A. V. I. carries out series of investigations among poultry producers, and the results are published in various documents. The main object of this work is to study the production cost and cost prices.

At the beginning, the investigations were empiric, but as the work proceeded, the data obtained enabled us to realize the first analysis of the cost-price of the egg production. The conception, sampling, collection of informations, supervision of questionnaires, have needed the contribution of several engineers and technicians.

At present, the investigations of the I. T. A. V. I. (permanent or conjunctural) deal with the production of broilers and other birds. New methods are used, such as « panels » allowing determinations of the continuous development of techniques, production costs and cost-prices.

As regards the egg production, it has been possible to determine the most fitted rearing and breeding conditions and to reduce the cost-price, in particular by defining the optimum size for the production units.

In the field of broiler production, the « panels » have been used to define accurately different important factors affecting the cost-price.

However, the work of the I. T. A. V. I. is not only to gather informations but, above all, to establish a permanent dialogue with the whole profession, allowing, for instance, important decisions to be taken such as changes in a given production system according to the general economic situation.
