Estimates of the annual genetic trends for average daily gain (g) and food conversion ratio (kg feed/kg gain) in the LW breed were $+2.9 \pm 0.8$ g and $-0.011 \pm 0.002$ kg/kg respectively in I stations, $-4.7 \pm 2.1$ g and $-0.008 \pm 0.003$ kg/kg respectively in P stations. The corresponding estimated for the FL breed were $+1.0 \pm 0.9$ g and $-0.008 \pm 0.003$ kg/kg respectively in I stations, $+3.2 \pm 2.7$ g and $-0.022 \pm 0.008$ kg/kg in P stations. For the BL breed, they were $-2.5 \pm 1.4$ g and $+0.003 \pm 0.004$ kg/kg respectively in I stations, $-0.8 \pm 2.8$ g and $-0.018 \pm 0.009$ kg/kg in P stations. Annual genetic trends in muscle content of the carcass (P stations) and average backfat thickness (I stations) were $+0.42 \pm 0.07$ p. 100 and $-0.26 \pm 0.02$ mm respectively for the LW breed, $+0.15 \pm 0.10$ p. 100 and $0.16 \pm 0.02$ mm for the FL breed, $-0.33 \pm 0.09$ p. 100 and $-0.19 \pm 0.03$ mm for the BL breed.

As compared to the expected responses from the boar selection index of I stations, estimated genetic gains were relatively greater for body composition than for growth traits.

**Genetic relationships between station performance-testing and « on-farm » testing in pigs**

Pig breeding for growth and carcass traits in France is based on performance recording both in central testing stations (S) and in breeding farms (F). Data collected in boar performance-test stations (1979-1983) and in the « on-farm » programme (1981-1983), on Large White and French Landrace pigs, were analysed in order to estimate genetic correlations between traits measured in the S and F environments. The S traits are average daily gain (ADG_S) and food conversion ratio (FCR_S) from 35 to 90 kg, and ultrasonic backfat thickness at 90 kg (BFT_S). The F traits are age at 100 kg (AGE_F) and ultrasonic backfat thickness at 100 kg (BFT_F). Data sets used for estimating genetic variances included 25298 boars from 4656 sires for S traits, and 96711 boars (1/3) or gilts (2/3) from 2292 sires for F traits (104 herds). Genetic covariances between S and F traits were derived from sire-offspring covariance on one hand (18325 F offspring from 302 S sires), and from paternal half-sib covariances on the other hand (1117 sires with 55697 F offspring and 5743 S sons). The pooled estimates of genetic correlation ($r_{ij}$) between S and F traits are as follows: $-0.41 \pm 0.07$ for ADG_S and AGE_F, $-0.10 \pm 0.05$ for ADG_S and BFT_F, $0.39 \pm 0.05$ for FCR_S and AGE_F, $0.23 \pm 0.05$ for FCR_S and BFT_F, $0.05 \pm 0.05$ for BFT_S and AGE_F, and $0.53 \pm 0.05$ for BFT_S and BFT_F. Separate analyses by sex of « on-farm » pigs suggest a genotype x sex interaction for growth traits, the $r_{ij}$'s being higher for the boar-boar than for the boar-gilt relationship ($-0.57 \pm 0.09$ vs $-0.35 \pm 0.06$ for ADG_S and AGE_F, and $0.61 \pm 0.09$ vs $0.31 \pm 0.06$ for FCR_S and AGE_F, respectively). The genotype x environment interaction effects explaining that the observed $r_{ij}$'s between similar S and F traits deviate from the « expected » value of 1 (or $-1$) are briefly discussed in relation to the feeding system, test period, sex and housing differences between the two breeding environments.
