Until now, cumulative gas production (Theodorou *et al*, 1994, Anim Feed Sci and Technol, 48, 185-197) has been used to assess different feedstuffs, using a standard source of inoculum. However, gas production could also potentially be used to compare the kinetics of fermentations from rumen or hindgut of different species and/or resulting from different diets, by testing the different inocula with standard feedstuffs. This study was conducted to determine whether gas production could be used to assess the kinetics of such fermentations.

Substrates were : wheat straw (WS), rye grass (RG), soya bean hulls (SBH), wheat (W), maize (M), and soya bean meal (SBM). The inocula were: sheep rumen fluid (SRF-hay diet), cattle rumen fluid (CRF-grass silage diet), cattle rumen fluid (CRF-grass silage + concentrate diet), and cattle faeces (CFF-grass silage diet). Proximate and fibre analyses were performed on all substrates. Cumulative gas production was measured (x 4), for a period of 144 hours. At the end of fermentation, DM losses were measured and samples taken for VFA analysis. The yield of gas (Y) was calculated as ml total gas/g DM disappeared. Gas data were then fitted to the mono-phasic curve  $Cumvol = A/(1 + (C/Time)^B)$  of Koops *et*

*al* (1995). An analysis of variance of the data (curve parameters and DM Losses) showed a highly significant interaction for substrate and inoculum ( $P < 0.01$ ). CFF had the poorest fermentative ability with the lowest % DM loss, lowest gas production (A), and the longest half-time (C). However, CFF ranked the substrates in roughly the same order as SRF, which is currently used as the standard inoculum in many centres. The patterns of degradation of the substrates did follow predictions to some extent ; eg WS was the most poorly degradable in terms of gas production and DM loss for all inocula, and had a consistently high gas yield. M and W were most similar, both in terms of their gas profiles and yields, and their DM losses. Most variation was seen in the ranking of RG, SBM, and SBH, in terms of their gas profiles (though not DM Loss) for the 4 inocula. SBM was the most interesting substrate, having a combination of low gas, and low yield, yet a high VFA concentration.

It was concluded that cumulative gas production has potential as a means to compare fermentations from different sources. However, a routine analysis of VFA at the end of the test period is recommended, to allow the detection of more subtle differences between the samples.

Mean Values	A (ml)	B(ml/h)	C(h)	Y(ml/g)	% DM Loss	Total VFA(mM)
<i>Inoculum</i>						
SRF (grass)	214.4	2.13	24.7	301.0	87.9	68.0
CRF (silage)	201.3	2.07	24.3	291.2	87.6	67.3
CRF (silage + conc)	227.0	2.11	25.8	331.2	87.8	72.2
CFF	193.1	2.03	31.0	286.1	85.5	69.7
MSD (P<0.05)	8.30	0.14	2.23	15.1	1.43	-
<i>Substrate</i>						
Wheat Straw	164.8	1.94	43.2	325.3	63.6	52.5
Rye Grass	208.0	1.75	21.9	319.2	82.3	67.1
Soya Bean Hulls	235.3	2.16	30.9	332.9	88.6	77.1
Wheat	233.2	2.36	19.9	305.4	96.2	69.7
Maize	240.0	2.43	24.3	316.0	94.9	75.6
