Knowledge of the mechanisms of synthesis and secretion of pancreatic enzymes in ruminants is poor compared to preruminants and mainly to monogastric animals, although understanding of these mechanisms may open ways to improve enzymatic degradation of food. The present experiment investigated the effects of meal on pancreatic exocrine secretion and on cholecystokinin (CCK), gastrin and secretin plasma levels of 60-120 d old ruminant calves. Four Holstein calves were fitted with two catheters into the pancreatic duct and in the duodenum, close to the pancreatic duct entry. The total pancreatic secretion was continuously collected and reintroduced into the intestine by means of a pump after constantly removing 7-8 % of juice for analysis (96 samples per day and 3 kinetics per calf). Twenty other calves were fitted with a jugular vein catheter and blood was taken at 0.5 h before meal and at 0.5, 1.0, 1.5, 2.0, 3.0, 4.0, 5.0 and 6.0 h after meal. All the animals were given once daily hay *ad libitum* and concentrate *ad libitum* up to a maximum of 3 kg.

The pancreatic juice secretion (13.4 ml/kg/d), which varied between animals (9.2 to 16.3 ml/kg/d) agreed with the estimated values reported by Ternouth *et al* (1977, Br J Nutr, 37, 237-249) and McCormick and Stewart (1967, J Dairy Sci, 50, 568-571) in calves and Taylor (1962, Res Vet Sci, 3, 63-77) in sheep. The daily kinetic indicated a postfeeding change neither in the rate of juice and protein flows nor in the protein concentration of the juice. However, as in sheep, secretions appeared to be the greatest at night and the protein flow

varied between animals (64 to 270 mg/kg/d). The lack of effect of the meal differed from the dramatic postprandial decrease of juice and protein secretions (down to 20 and 33 % of the prefeeding values, respectively) and the large increase of protein concentration (up to 250 % of the prefeeding value) we observed between 1 to 2 hours after meal in milk-fed calves (Le Huërou-Luron *et al*, 1994, Proc Soc Nutr Physiol, 3, 298). The mean plasma levels of secretin, gastrin and CCK which were 16, 76 and 99 pg/ml before feeding showed no variation after the meal ; in contrast, plasma secretin decreased while CCK and gastrin increased postprandially in preruminants (Toullec *et al*, 1992, Comp Biochem Physiol, 102A, 203-209).

Secretin and CCK are known to be involve in the regulation of the pancreatic juice flow and of the protein concentration, respectively. Furthermore, in ruminant calves, CCK B/gastrin receptor subtype which has similar affinities for CCK and gastrin, were more expressed than the CCK A subtype which has a much greater affinity for CCK than for gastrin (Guilloteau *et al*, 1994, Proc Soc Nutr Physiol, 3, 289-290), suggesting a regulatory role of gastrin on pancreatic function. Therefore, the postprandial constancy of pancreatic juice flow and protein concentration observed in ruminant calves during the present experiment, could be related to the similar trend recorded for plasma secretin, gastrin and CCK. That could be explained by the more regular stomach distension and flow rate of digesta than in preruminant calves.
